

# 01-SpringBoot高级-今日内容

- SpringBoot自定配置
- SpringBoot事件监听
- SpringBoot流程分析
- SpringBoot监控
- SpringBoot部署

## 02-SpringBoot自动配置-Condition-1

Condition是Spring4.0后引入的条件化配置接口，通过实现Condition接口可以完成有条件的加载相应的Bean

@Conditional要配和Condition的实现类（ClassCondition） 进行使用

- ClassCondition

```
public class ClassCondition implements Condition {
    /**
     *
     * @param context 上下文对象。用于获取环境，IOC容器，ClassLoader对象
     * @param metadata 注解元对象。 可以用于获取注解定义的属性值
     * @return
     */
    @Override
    public boolean matches(ConditionContext context, AnnotatedTypeMetadata
metadata) {

        //1.需求： 导入Jedis坐标后创建Bean
        //思路： 判断redis.clients.jedis.Jedis.class文件是否存在
        boolean flag = true;
        try {
            Class<?> cls = Class.forName("redis.clients.jedis.Jedis");
        } catch (ClassNotFoundException e) {
            flag = false;
        }
        return flag;
    }
}
```

- UserConfig

```

@Configuration
public class UserConfig {

    @Bean
    @Conditional(ClassCondition.class)
    public User user(){
        return new User();
    }

}

```

测试

```

@SpringBootApplication
public class SpringbootConditionApplication {

    public static void main(String[] args) {
        //启动SpringBoot的应用，返回Spring的IOC容器
        ConfigurableApplicationContext context =
        SpringApplication.run(SpringbootConditionApplication.class, args);

        Object user = context.getBean("user");
        System.out.println(user);

    }

}

```

## 03-SpringBoot自动配置-Condition-2

需求：将类的判断定义为动态的。判断哪个字节码文件存在可以动态指定。

自定义条件注解类

```

import org.springframework.context.annotation.Conditional;

import java.lang.annotation.*;

@Target({ElementType.TYPE, ElementType.METHOD})
@Retention(RetentionPolicy.RUNTIME)
@Documented
@Conditional(ClassCondition.class)
public @interface ConditionOnClass {
    String[] value();
}

```

**注意：**此处@ConditionOnClass为自定义注解

```

@Configuration
public class UserConfig {

    @Bean
    //@Conditional(ClassCondition.class)
    @ConditionOnClass("com.alibaba.fastjson.JSON")

```

```
public User user(){
    return new User();
}

@Bean
@ConditionalOnProperty(name = "itcast",havingValue = "itheima")
public User user2(){
    return new User();
}

}
```

测试User对象的创建

```
@SpringBootApplication
public class SpringbootConditionApplication {

    public static void main(String[] args) {
        //启动SpringBoot的应用，返回Spring的IOC容器
        ConfigurableApplicationContext context =
        SpringApplication.run(SpringbootConditionApplication.class, args);

        Object user = context.getBean("user");
        System.out.println(user);

    }

}
```

[查看条件注解源码](#)

### SpringBoot 提供的常用条件注解:

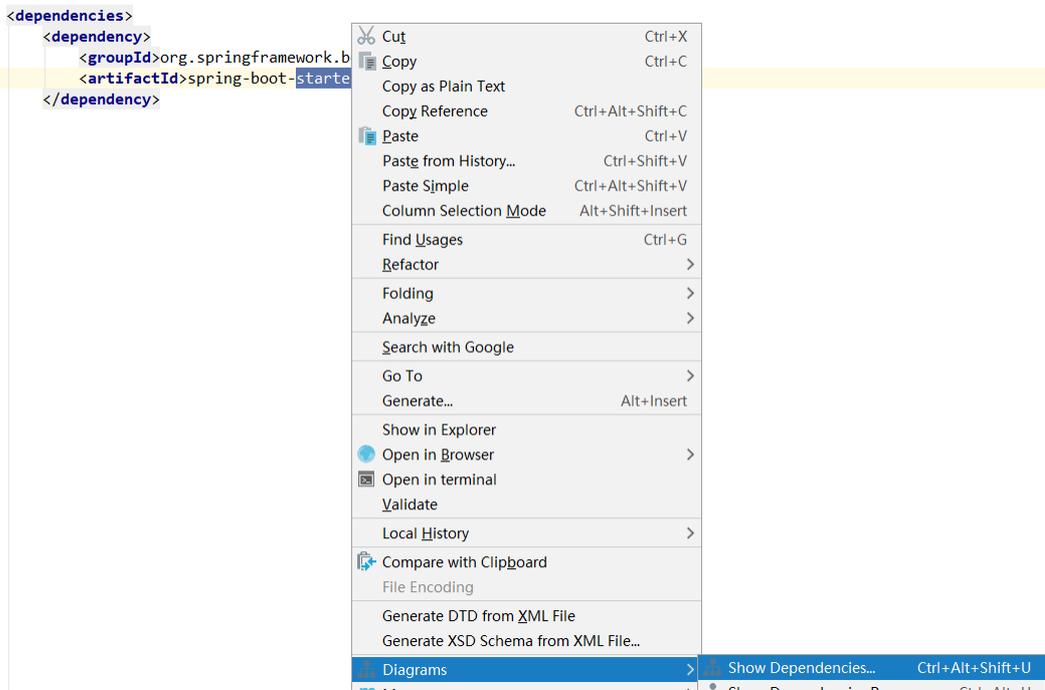

ConditionalOnProperty: 判断配置文件中是否有对应属性和值才初始化Bean

ConditionalOnClass: 判断环境中是否有对应字节码文件才初始化Bean

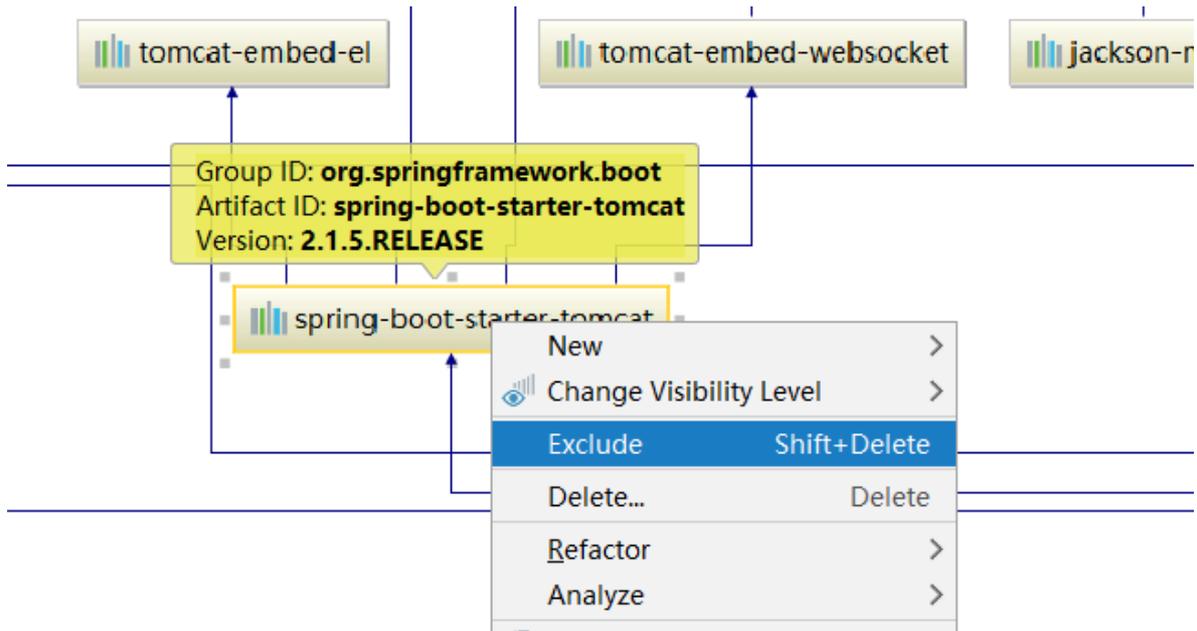

ConditionalOnMissingBean: 判断环境中没有对应Bean才初始化Bean

## 04-SpringBoot自动配置-切换内置web服务器

[查看继承关系图](#)

排除Tomcat

pom文件中的排除依赖效果

```

<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-web</artifactId>
  <!--排除tomcat依赖-->
  <exclusions>
    <exclusion>
      <artifactId>spring-boot-starter-tomcat</artifactId>
      <groupId>org.springframework.boot</groupId>
    </exclusion>
  </exclusions>
</dependency>

```

```
<!--引入jetty的依赖-->
<dependency>
  <artifactId>spring-boot-starter-jetty</artifactId>
  <groupId>org.springframework.boot</groupId>
</dependency>
```

## 05-SpringBoot自动配置-Enable注解原理

- SpringBoot不能直接获取在其他工程中定义的Bean

演示代码:

springboot-enable工程

```
/**
 * @ComponentScan 扫描范围: 当前引导类所在包及其子包
 *
 * com.itheima.springbootenable
 * com.itheima.config
 * //1. 使用@ComponentScan扫描com.itheima.config包
 * //2. 可以使用@Import注解, 加载类。这些类都会被Spring创建, 并放入IOC容器
 * //3. 可以对Import注解进行封装。
 */

//@ComponentScan("com.itheima.config")
//@Import(UserConfig.class)
@EnableUser
@SpringBootApplication
public class SpringbootEnableApplication {

    public static void main(String[] args) {
        ConfigurableApplicationContext context =
        SpringApplication.run(SpringbootEnableApplication.class, args);

        //获取Bean
        Object user = context.getBean("user");
        System.out.println(user);

    }

}
```

pom中引入springboot-enable-other

```
<dependency>
  <groupId>com.itheima</groupId>
  <artifactId>springboot-enable-other</artifactId>
  <version>0.0.1-SNAPSHOT</version>
</dependency>
```

springboot-enable-other工程

**UserConfig**

```

@Configuration
public class UserConfig {

    @Bean
    public User user() {
        return new User();
    }

}

```

## EnableUser注解类

```

import org.springframework.context.annotation.Import;

import java.lang.annotation.*;

@Target(ElementType.TYPE)
@Retention(RetentionPolicy.RUNTIME)
@Documented
@Import(UserConfig.class)
public @interface EnableUser {

```

```

}

```

**\*\*原因\*\***: @ComponentScan 扫描范围: 当前引导类所在包及其子包

**\*\*三种解决方案\*\***:

1. 使用@ComponentScan扫描com.itheima.config包
2. 可以使用@Import注解, 加载类。这些类都会被Spring创建, 并放入IOC容器
3. 可以对Import注解进行封装。

**\*\*重点: Enable注解底层原理是使用@Import注解实现Bean的动态加载\*\***

**## \*\*06-SpringBoot自动配置-@Import详解\*\***

@Enable\*底层依赖于@Import注解导入一些类, 使用@Import导入的类会被Spring加载到IOC容器中。而@Import提供4中用法:

①导入Bean

②导入配置类

③导入 ImportSelector 实现类。一般用于加载配置文件中的类

④导入 ImportBeanDefinitionRegistrar 实现类。

- 导入Bean @Import(User.class)

- 导入配置类 @Import(UserConfig.class)

- 导入 ImportSelector 实现类 @Import(MyImportSelector.class)

MyImportSelector

```
```java
public class MyImportSelector implements ImportSelector {
    @Override
    public String[] selectImports(AnnotationMetadata importingClassMetadata) {
        return new String[]{"com.itheima.domain.User",
            "com.itheima.domain.Role"};
    }
}
```

- 导入 ImportBeanDefinitionRegistrar 实现类。  
@Import({MyImportBeanDefinitionRegistrar.class})

```
public class MyImportBeanDefinitionRegistrar implements
ImportBeanDefinitionRegistrar {
    @Override
    public void registerBeanDefinitions(AnnotationMetadata
importingClassMetadata, BeanDefinitionRegistry registry) {
        AbstractBeanDefinition beanDefinition =
BeanDefinitionBuilder.rootBeanDefinition(User.class).getBeanDefinition();
        registry.registerBeanDefinition("user", beanDefinition);
    }
}
```

SpringbootEnableApplication测试代码

```
/**
```

- Import4中用法:
  - 1. 导入Bean
  - 2. 导入配置类
  - 3. 导入ImportSelector的实现类。
  - 4. 导入ImportBeanDefinitionRegistrar实现类

```
/*@Import(User.class)
/*@Import(UserConfig.class)
/*@Import(MyImportSelector.class)
/*@Import({MyImportBeanDefinitionRegistrar.class})
```

```
@SpringBootApplication
public class SpringbootEnableApplication {
```

```
    public static void main(String[] args) {
        ConfigurableApplicationContext context =
SpringApplication.run(SpringbootEnableApplication.class, args);

        /**//获取Bean
```

```

Object user = context.getBean("user");
System.out.println(user);*/

/*User user = context.getBean(User.class);
System.out.println(user);

Role role = context.getBean(Role.class);
System.out.println(role);*/

/* Object user = context.getBean("user");
System.out.println(user);*/
Map<String, User> map = context.getBeansOfType(User.class);
System.out.println(map);

}

```

```

}

```

@EnableAutoConfiguration中使用的是第三种方式:

@Import(AutoConfigurationImportSelector.class)

## \*\*07-SpringBoot自动配置-@EnableAutoConfiguration详解\*\*

![1571387384701](img/1571387384701.png)

- @EnableAutoConfiguration 注解内部使用

@Import(AutoConfigurationImportSelector.\*\*class\*\*)来加载配置类。

- 配置文件位置: META-INF/spring.factories, 该配置文件中定义了大量的配置类, 当 SpringBoot 应用启动时, 会自动加载这些配置类, 初始化Bean

- 并不是所有的Bean都会被初始化, 在配置类中使用Condition来加载满足条件的Bean

## \*\*08-SpringBoot自动配置-自定义starter步骤分析\*\*

\*\*需求:\*\* 自定义redis-starter。要求当导入redis坐标时, SpringBoot自动创建Jedis的Bean。

\*\*步骤:\*\*

①创建 redis-spring-boot-autoconfigure 模块

②创建 redis-spring-boot-starter 模块, 依赖 redis-spring-boot-autoconfigure的模块

③在 redis-spring-boot-autoconfigure 模块中初始化 Jedis 的 Bean。并定义META-INF/spring.factories 文件

④在测试模块中引入自定义的 redis-starter 依赖, 测试获取 Jedis 的Bean, 操作 redis。

## \*\*09-SpringBoot自动配置-自定义starter实现-1\*\*

1. \*\*创建redis-spring-boot-starter工程\*\*

- pom文件中引入redis-spring-boot-autoconfigure

```
```\xml
<!--引入configure-->
  <dependency>
    <groupId>com.itheima</groupId>
    <artifactId>redis-spring-boot-autoconfigure</artifactId>
    <version>0.0.1-SNAPSHOT</version>
  </dependency>
```

## 2. 创建redis-spring-boot-autoconfigure配置工程

创建RedisProperties配置文件参数绑定类

```
@ConfigurationProperties(prefix = "redis")
public class RedisProperties {

    private String host = "localhost";
    private int port = 6379;

    public String getHost() {
        return host;
    }

    public void setHost(String host) {
        this.host = host;
    }

    public int getPort() {
        return port;
    }

    public void setPort(int port) {
        this.port = port;
    }
}
```

创建RedisAutoConfiguration自动配置类

```
@Configuration
@EnableConfigurationProperties(RedisProperties.class)
public class RedisAutoConfiguration {

    /**
     * 提供Jedis的bean
     */
    @Bean
    public Jedis jedis(RedisProperties redisProperties) {

        return new Jedis(redisProperties.getHost(), redisProperties.getPort());
    }
}
```

在resource目录下创建META-INF文件夹并创建spring.factories

注意：“\”是换行使用的

```
org.springframework.boot.autoconfigure.EnableAutoConfiguration=\
com.itheima.redis.config.RedisAutoConfiguration
```

### 3. 在springboot-enable工程中引入自定义的redis的starter

```
<!--自定义的redis的starter-->
<dependency>
  <groupId>com.itheima</groupId>
  <artifactId>redis-spring-boot-starter</artifactId>
  <version>0.0.1-SNAPSHOT</version>
</dependency>
```

在SpringbootEnableApplication启动类中测试

```
Jedis jedis = context.getBean(Jedis.class);
System.out.println(jedis);
```

## 10-SpringBoot自动配置-自定义starter实现-2

测试springboot-enable工程中的application.properties中的配置参数

```
redis.port=6666
```

使用注解完成有条件加载配置类

```
@Configuration
@EnableConfigurationProperties(RedisProperties.class)
@ConditionalOnClass(Jedis.class)
public class RedisAutoConfiguration {

    /**
     * 提供Jedis的bean
     */
    @Bean
    @ConditionalOnMissingBean(name = "jedis")
    public Jedis jedis(RedisProperties redisProperties) {
        System.out.println("RedisAutoConfiguration...");
        return new Jedis(redisProperties.getHost(), redisProperties.getPort());
    }
}
```

## 11-SpringBoot事件监听

Java中的事件监听机制定义了以下几个角色：

①事件：Event，继承 java.util.EventObject 类的对象

②事件源：Source，任意对象Object

③监听器：Listener，实现 java.util.EventListener 接口的对象

SpringBoot 在项目启动时，会对几个监听器进行回调，我们可以实现这些监听器接口，在项目启动时完成一些操作。

- ApplicationContextInitializer、
- SpringApplicationRunListener、
- CommandLineRunner、
- ApplicationRunner

自定义监听器的启动时机：MyApplicationRunner和MyCommandLineRunner都是当项目启动后执行，使用@Component放入容器即可使用

MyApplicationRunner

```
/**
 * 当项目启动后执行run方法。
 */
@Component
public class MyApplicationRunner implements ApplicationRunner {
    @Override
    public void run(ApplicationArguments args) throws Exception {
        System.out.println("ApplicationRunner...run");
        System.out.println(Arrays.asList(args.getSourceArgs()));
    }
}
```

MyCommandLineRunner

```
@Component
public class MyCommandLineRunner implements CommandLineRunner {
    @Override
    public void run(String... args) throws Exception {
        System.out.println("CommandLineRunner...run");
        System.out.println(Arrays.asList(args));
    }
}
```

MyApplicationContextInitializer的使用要在resource文件夹下添加META-INF/spring.factories

```
org.springframework.context.ApplicationContextInitializer=com.itheima.springboot.listener.listener.MyApplicationContextInitializer
```

```
@Component
public class MyApplicationContextInitializer implements
ApplicationContextInitializer {
    @Override
    public void initialize(ConfigurableApplicationContext applicationContext) {
        System.out.println("ApplicationContextInitializer...initialize");
    }
}
```

MySpringApplicationRunListener的使用要添加**构造器**

```
public class MySpringApplicationRunListener implements
SpringApplicationRunListener {

    public MySpringApplicationRunListener(SpringApplication application,
String[] args) {
    }

    @Override
    public void starting() {
        System.out.println("starting...项目启动中");
    }

    @Override
    public void environmentPrepared(ConfigurableEnvironment environment) {
        System.out.println("environmentPrepared...环境对象开始准备");
    }

    @Override
    public void contextPrepared(ConfigurableApplicationContext context) {
        System.out.println("contextPrepared...上下文对象开始准备");
    }

    @Override
    public void contextLoaded(ConfigurableApplicationContext context) {
        System.out.println("contextLoaded...上下文对象开始加载");
    }

    @Override
    public void started(ConfigurableApplicationContext context) {
        System.out.println("started...上下文对象加载完成");
    }

    @Override
    public void running(ConfigurableApplicationContext context) {
        System.out.println("running...项目启动完成, 开始运行");
    }

    @Override
    public void failed(ConfigurableApplicationContext context, Throwable
exception) {
        System.out.println("failed...项目启动失败");
    }
}
```

## 12-SpringBoot流程分析-初始化

1. 配置启动引导类（判断是否有启动主类）
2. 判断是否是Web环境
3. 获取初始化类、监听器类

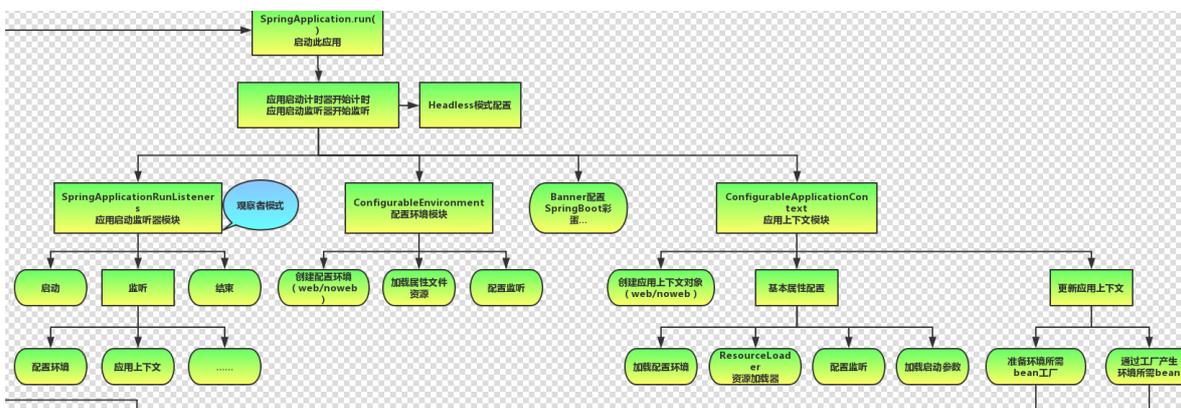

## 13-SpringBoot流程分析-run

1. 启动计时器
2. 执行监听器
3. 准备环境
4. 打印banner: 可以在resource下粘贴自定义的banner
5. 创建context

```
refreshContext(context);
```

执行refreshContext方法后才真正创建Bean

## 14-SpringBoot监控-actuator基本使用

## ①导入依赖坐标

```
<dependency>

  <groupId>org.springframework.boot</groupId>

  <artifactId>spring-boot-starter-actuator</artifactId>

</dependency>
```

## ②访问<http://localhost:8080/acruator>

```
{
  "_links":{
    "self":{
      "href":"http://localhost:8080/actuator",
      "templated":false
    },
    "health":{
      "href":"http://localhost:8080/actuator/health",
      "templated":false
    },
    "health-component-instance": {
      "href":"http://localhost:8080/actuator/health/{component}/{instance}",
      "templated":true
    },
    "health-component": {
      "href":"http://localhost:8080/actuator/health/{component}",
      "templated":true
    },
    "info":{
      "href":"http://localhost:8080/actuator/info",
      "templated":false
    }
  }
}
```

<http://localhost:8080/actuator/info>

在application.properties中配置

```
info.name=lucy
info.age=99
```

<http://localhost:8080/actuator/health>

开启健康检查详细信息

```
management.endpoint.health.show-details=always
```

```
{
  "status":"UP",
```

```
"details":{
  "diskSpace":{
    "status":"UP",
    "details":{
      "total":159579508736,
      "free":13558104064,
      "threshold":10485760
    }
  },
  "redis":{
    "status":"UP",
    "details":{
      "version":"2.4.5"
    }
  }
}
}
```

## 15-SpringBoot监控-actuator开启所有endpoint

开启所有endpoint

在application.properties中配置:

```
management.endpoints.web.exposure.include=*
```

开启所有endpoint的返回结果:

```
{
  "_links":{
    "self":{
      "href":"http://localhost:8080/actuator",
      "templated":false
    },
    "auditevents":{
      "href":"http://localhost:8080/actuator/auditevents",
      "templated":false
    },
    "beans":{
      "href":"http://localhost:8080/actuator/beans",
      "templated":false
    },
    "caches-cache":{
      "href":"http://localhost:8080/actuator/caches/{cache}",
      "templated":true
    },
    "caches":{
      "href":"http://localhost:8080/actuator/caches",
      "templated":false
    },
    "health-component-instance":{
      "href":"http://localhost:8080/actuator/health/{component}/{instance}",
      "templated":true
    },
    "health":{

```

```
    "href":"http://localhost:8080/actuator/health",
    "templated":false
  },
  "health-component":{
    "href":"http://localhost:8080/actuator/health/{component}",
    "templated":true
  },
  "conditions":{
    "href":"http://localhost:8080/actuator/conditions",
    "templated":false
  },
  "configprops":{
    "href":"http://localhost:8080/actuator/configprops",
    "templated":false
  },
  "env":{
    "href":"http://localhost:8080/actuator/env",
    "templated":false
  },
  "env-toMatch":{
    "href":"http://localhost:8080/actuator/env/{toMatch}",
    "templated":true
  },
  "info":{
    "href":"http://localhost:8080/actuator/info",
    "templated":false
  },
  "loggers":{
    "href":"http://localhost:8080/actuator/loggers",
    "templated":false
  },
  "loggers-name":{
    "href":"http://localhost:8080/actuator/loggers/{name}",
    "templated":true
  },
  "heapdump":{
    "href":"http://localhost:8080/actuator/heapdump",
    "templated":false
  },
  "threaddump":{
    "href":"http://localhost:8080/actuator/threaddump",
    "templated":false
  },
  "metrics-requiredMetricName":{
    "href":"http://localhost:8080/actuator/metrics/{requiredMetricName}",
    "templated":true
  },
  "metrics":{
    "href":"http://localhost:8080/actuator/metrics",
    "templated":false
  },
  "scheduledtasks":{
    "href":"http://localhost:8080/actuator/scheduledtasks",
    "templated":false
  },
  "httptrace":{
    "href":"http://localhost:8080/actuator/httptrace",
```

```
        "templated":false
    },
    "mappings":{
        "href":"http://localhost:8080/actuator/mappings",
        "templated":false
    }
}
}
```

## 16-SpringBoot监控-springboot admin图形化界面使用

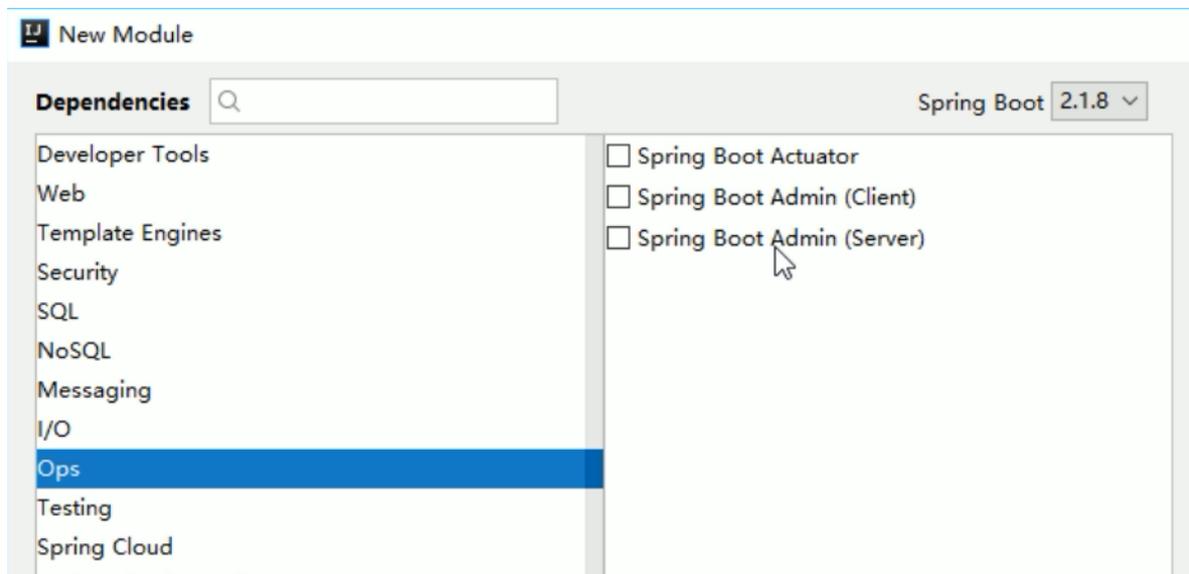

SpringBoot Admin 有两个角色，客户端(Client)和服务端(Server)。

以下为创建服务端和客户端工程步骤：

admin-server:

①创建 admin-server 模块

②导入依赖坐标 admin-starter-server

```
<dependency>
  <groupId>de.codecentric</groupId>
  <artifactId>spring-boot-admin-starter-server</artifactId>
</dependency>
```

③在引导类上启用监控功能@EnableAdminServer

```
@EnableAdminServer
@SpringBootApplication
public class SpringbootAdminServerApplication {

    public static void main(String[] args) {
        SpringApplication.run(SpringbootAdminServerApplication.class, args);
    }

}
```

admin-client:

①创建 admin-client 模块

②导入依赖坐标 admin-starter-client

```
<dependency>
  <groupId>de.codecentric</groupId>
  <artifactId>spring-boot-admin-starter-client</artifactId>
</dependency>
```

③配置相关信息: server地址等

```
# 执行admin.server地址
spring.boot.admin.client.url=http://localhost:9000

management.endpoint.health.show-details=always
management.endpoints.web.exposure.include=*
```

④启动server和client服务, 访问server

## 17-SpringBoot部署

SpringBoot 项目开发完毕后, 支持两种方式部署到服务器:

①jar包(官方推荐)

②war包

**更改pom文件中的打包方式为war**

修改启动类

```
import org.springframework.boot.SpringApplication;
import org.springframework.boot.autoconfigure.SpringBootApplication;
import org.springframework.boot.builder.SpringApplicationBuilder;
import
org.springframework.boot.web.servlet.support.SpringBootServletInitializer;

@SpringBootApplication
public class SpringbootDeployApplication extends SpringBootServletInitializer {

    public static void main(String[] args) {
        SpringApplication.run(SpringbootDeployApplication.class, args);
    }

    @Override
    protected SpringApplicationBuilder configure(SpringApplicationBuilder
builder) {
        return builder.sources(SpringbootDeployApplication.class);
    }
}
```

指定打包的名称

```
<build>
  <finalName>springboot</finalName>
  <plugins>
    <plugin>
      <groupId>org.springframework.boot</groupId>
      <artifactId>spring-boot-maven-plugin</artifactId>
    </plugin>
  </plugins>
</build>
```
